The user would enter a search string and the result should be displayed as JSON. My question is what is the best/easiest way to search through the JSON and find the string matching the search string. One of the way I thought of doing is parsing the JSON and loop through each JSON object and try to match the search string. If match is found then return the JSON object. Is there any other way to do the same? A: It seems that, for your particular task, you have few problems: searching through JSON is basically the same as searching through key-value pairs - you can easily do this with Jackson. matching strings is not something JSON cannot do, it's just that in your case you may have to figure out some sort of scoring system. Here's how you could do it: Check if a given string is contained in JSON string For each string in the JSON string, check if it contains the searched string If the string is found, check if it's a substring of the one you are searching a1d647c40b
