The times are a-changin': depression and coping strategies in young adults. The purpose of this study is to evaluate young adults (N = 177, Mage = 19.5 years old) as they experience a stressful life change: moving from high school to college. We explore how these adults cope with this significant event in their lives. Young adults' self-reports revealed that they experienced intrusive thoughts and feelings about the school-to-college transition, which interfered with their ability to function and was stressful for those who experienced a change in social networks and resources. Although significantly less experiencing stress, the results of multivariate analyses revealed that young adults who experienced a larger drop in social networks and fewer resources before and after the school-to-college transition reported a higher incidence of internalizing symptoms of depression, compared with those who did not experience a change. Additionally, only those who experienced a drop in both social resources and social networks reported significant increases in symptoms of depression. The current findings suggest that the size of the drop in social networks and resources may be an important predictor of depression among young adults. These results can assist in the development of interventions to promote resilience among college students. Pieter Claesz the Elder Pieter Claesz the Elder (c. 1550 - 1619) was a Dutch painter of the Northern Netherlands school. He is known for his battle scenes and for his portrait of the Adoration of the Shepherds, which is now in the National Gallery in London. In some converged network environments, a virtual local area network (VLAN) is implemented in which untagged virtual devices may reside on different physical machines. In some cases, a converged network environment may comprise a server layer and a VLAN network layer. The VLAN network layer may provide a logical layer for other network functions such as for example, Quality of Service (QoS) and delivery of multicast traffic, which is different from the server layer that provides routing and delivery of unicast traffic. In some converged network environments, the server layer and the VLAN layer may be implemented by different software components that intercommunicate via messaging. In some converged networks, different virtual devices in the VLAN layer may utilize different messaging systems or similar messaging structures. For example, one virtual device within the VLAN layer may utilize one messaging system for data packets that are destined for that virtual device, while another virtual device within the VLAN layer may utilize another messaging system for data packets that are destined for that virtual device. As used herein, a messaging system is software that manages the delivery of data packets from one or more source machines to one or more destination machines. When a source machine sends a data packet to the VLAN layer, the source machine needs to know which destination virtual device the data packet should be delivered to. The source machine can send a "piggybacked" data packet to the VLAN layer that includes the destination virtual device as its "payload". The data packet may be piggybacked because the VLAN layer can extract the destination virtual device from the data packet. The VLAN layer may then process the data packet and determine which virtual device should
